Overfitting

OVERFITTING IS THE PRODUCTION OF AN ANALYSIS THAT CORRESPONDS TOO CLOSELY OR EXACTLY TO A PARTICULAR SET OF DATA, AND MAY THEREFORE FAIL TO FIT ADDITIONAL DATA OR PREDICT FUTURE OBSERVATIONS RELIABLY. [OXFORDDICTIONARIES]

Housing Prices Example

Deal with Overfitting:

Two Options:

1. Reduce number of features
2. Regularization
 - Keep all the features
 - Reduce magnitude or values of parameters

Cost Function

If we have over fitting in our hypothesis function we can reduce the weight for some terms in our function by increasing the cost.

$$\theta_0 + \theta_1 x + \theta_2 x^2$$

$$\theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$$

Suppose we penalize and make θ_3, θ_4 really small.

$$\min_{\theta} \frac{1}{2m} \sum_{i=1}^m (h_{\theta})(x^{(i)}) - y^{(i)})$$

Cost Function

Small values for parameters $\theta_0, \theta_0, \theta_1, \theta_2, \dots, \theta_n$

- "Simpler" hypothesis
- Less prone to overfitting

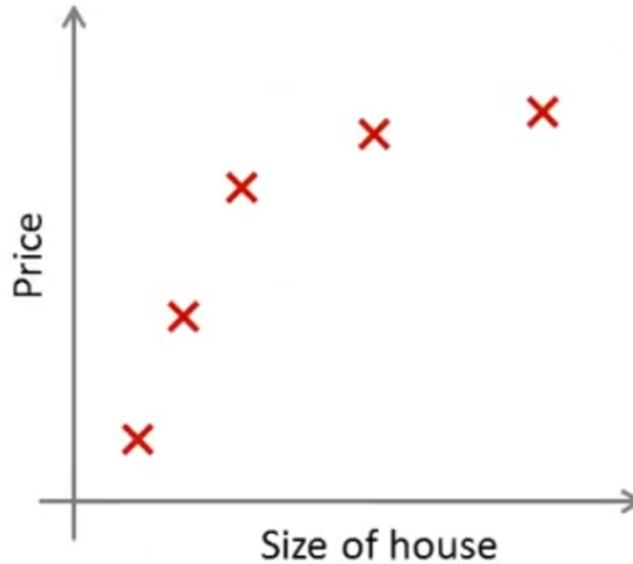

Housing:

- Features: x_1, x_2, \dots, x_{100}
- Parameters: $\theta_0, \theta_0, \theta_1, \theta_2, \dots, \theta_n$

$$\min_{\theta} \frac{1}{2m} \sum_{i=1}^m (h_{\theta})(x^{(i)} - y^{(i)})$$

Cost Function

$$J(\theta) = \frac{1}{2m} [\sum_{i=1}^m (h_{\theta}(x^i)^2 + \lambda \sum_{j=1}^n \theta_j^2]$$

[Home Page](#)[Title Page](#)[<<](#)[>>](#)[<](#)[>](#)[Page 12 of 21](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

Cost Function

In regularized linear regression, we choose to minimize

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^i); 2 + \lambda \sum_{j=1}^n \theta_j^2) \right]$$

What happen if we set λ to a large number (e.g $\lambda = 10^{10}$)?

Cost Function

What happen if we set λ to a large number (e.g $\lambda = 10^{10}$)?

$$J(\theta) = \frac{1}{2m} [\sum_{i=1}^m (h_{\theta}(x^i); 2 + \lambda \sum_{j=1}^n \theta_j^2]$$

- Algorithm works fine; setting λ to be large can't hurt it.
- Algorithm fails to eliminate overfitting.
- Algorithm results in underfitting. (Fails to fit even training data).
- Gradient descent will fail to converge.

1. Regularized linear regression

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n \theta_j^2 \right]$$

$$\min_{\theta} J(\theta)$$

2. Gradient descent

Repeat {

$$\theta_0 := \theta_0 - \alpha \frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_0^{(i)}$$

$$\theta_j := \theta_j - \alpha \frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

$(j = 0, 1, 2, 3, \dots, n)$

}

$$\theta_j := \theta_j (1 - \alpha \frac{\lambda}{m}) - \alpha \frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

Regularized logistic regression

3. Regularized logistic regression

$$h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_1^2 x_2 + \theta_4 x_1^2 x_2^2 + \theta_5 x_1^2 x_2^3 + \dots)$$

Cost function:

$$J(\theta) = - \left[\frac{1}{m} \sum_{i=1}^m y^{(i)} \log h_{\theta}(x^{(i)}) + (1 - y^{(i)}) \log (1 - h_{\theta}(x^{(i)})) \right]$$
